STATUS OF CORAL REEFS OF LITTLE CAYMAN AND GRAND CAYMAN, BRITISH WEST INDIES, IN 1999 (PART 2: FISHES)

BY

CHRISTY V. PATTENGILL-SEMMENS¹ and BRICE X. SEMMENS²

ABSTRACT

The fish assemblages at 33 sites around the islands of Grand Cayman and Little Cayman were assessed in June 1999 for the Atlantic and Gulf Rapid Reef Assessment initiative using belt transects and Roving Diver Technique surveys. A comprehensive species list, with 58 new records, was compiled for the Cayman Islands based on these data and survey data from the Reef Environmental Education Foundation database. In general, the reefs on Little Cayman appeared to support larger and more individual fishes than those of Grand Cayman. A multidimensional scaling ordination plot showed no clear island pattern but did reveal that the windward or leeward location of each site was an important factor affecting fish community composition. All but two sites followed a pattern of distinct windward and leeward clusters, and these clusters also correlated to macroalgal abundance. The relationship between macroalgal abundance and herbivore density was analyzed and significant correlations were found with surgeonfishes (Acanthuridae) and parrotfishes (Scaridae) using multiple regression.

INTRODUCTION

Fishes have the potential to provide sensitive indices of reef health. Certain predatory fish species dominate the top of coral reef food webs, hence their density reflects a vast number of human and natural disturbances from habitat alteration to direct exploitation (Ferreira et al., 1998). Similarly, the presence and abundance of herbivorous fishes affect algal composition and cover (Ogden and Lobel, 1978).

In response to concerns about the widespread deterioration of reef condition in the Caribbean basin, the Atlantic and Gulf Rapid Reef Assessment (AGRRA) initiative was designed to provide a regional perspective using a standardized methodology. The rapid assessment protocol is focused on three main components of the reef community: stony corals, fish, and algae. As part of this initiative, the reefs of Grand Cayman (GC) and Little Cayman (LC) were assessed in June 1999.

The Cayman Islands are a British Crown Colony located in the western Caribbean. The three islands lie between 19° 15' and 19° 45' N latitude and between 79° 44' and 81° 27' W longitude (Fig. 1). GC is the largest and most populous. LC lies approximately 145 km to its east-northeast and is about 10 km from Cayman Brac. The three islands are limestone, horst-and-graben structures associated with the Cayman Ridge (Jones, 1994). Freshwater is scarce and the islands lack rivers and streams. The fringing reefs that surround most of the islands contain shallow reef crests (rubble ramparts) as well as mid-shelf and shelf-edge fore reefs (Blanchon and Jones, 1997). These fringing reefs are particularly well-developed on the windward (eastern and southern) coasts of both islands. Other submerged benthic habitats include seagrass beds and mangrove fringes.

The level of human disturbance on GC is significantly greater than on LC, which is relatively remote and undeveloped. Anthropogenic impacts on GC reefs include habitat destruction from anchors and increased suspended sediment load from dredging and mangrove removal. Fishing pressure is considerably greater on GC than around LC. Five spawning aggregations of Nassau grouper (*Epinephelus striatus*) have been heavily harvested (during the 2002 spawning season, all but one had been depleted). Five hundred local residents are licensed to snorkel with spearguns. Fish pots (Antillean Z-traps) probably represent the biggest threat to the fish communities of both islands (personal observations).

An extensive marine park system was established in the Cayman Islands in 1986. Reefs in marine park and replenishment zone areas are protected from fish traps, spearguns, anchoring, and line fishing, although line fishing from shore and beyond the drop-off (shelf edge) is allowed. The Cayman Islands' Department of the Environment maintains a system of 257 permanent mooring buoys throughout the three islands.

The benthos of the Cayman Islands has been well studied, including descriptions of the coral communities, reef status, and analysis of spatial patterns (Roberts, 1988; Logan, 1994; Roberts, 1994). In contrast, apart from descriptions of Nassau grouper spawning aggregations (Colin et al., 1987; Tucker et al., 1993), there are few scientific descriptions of its reef fishes. However, Burgess et al.'s (1994) taxonomic review of collection expeditions contained an annotated list of 381 species known to occur in the Cayman Islands, including the endemic y-lined blenny (*Starksia y-lineata*) described by Gilbert (1965).

Since 1994, fish sighting and relative abundance data have been collected around the Cayman Islands as part of the Reef Environmental Education Foundation (REEF) Fish Survey Project, an ongoing volunteer monitoring effort. REEF volunteers use the Roving Diver Technique (RDT) (Schmitt and Sullivan, 1996) and the survey data are maintained in a publicly-accessible database. By the end of 2001, the REEF database contained over 40,000 surveys from over 2,000 sites, including approximately 2,200 surveys from the Cayman Islands.

This paper describes the fish assemblages of the Cayman Islands using the 1999 AGRRA data for GC and LC, along with REEF data from the two islands collected between 1994 and 2001. An updated species list and comparisons between islands and among sites are provided. The relationship between herbivorous fishes and macroalgal abundance is also investigated.

METHODS

In June 1999, AGRRA fish and benthos surveys were simultaneously conducted at 15 sites on GC and 18 sites on LC (Fig. 1, Table 1). Sites were chosen by a mixed representative/strategic strategy: 12 were on the windward sides of the islands and 21 were on their leeward sides (the southwest side of GC was underrepresented). Six sites on LC and three on GC were located within marine park or replenishment zone areas. The benthic component is reported by Manfrino et al. (this volume). To assess the fishes, the AGRRA protocol Version 2.1 was used (Appendix One, this volume). At each site, a team of three (occasionally two) divers conducted at least 10 2 m x 30 m belt transects. Counts of serranids (groupers) were restricted to species of *Epinephelus* and *Mycteroperca*; scarids (parrotfishes) and haemulids (grunts) less than 5 cm in length were not tallied. Each diver also conducted a 45-60 minute RDT survey at each site. All fieldwork was undertaken between 9:00 a.m. and 3:00 p.m. Field identifications were based on Humann (1994), Stokes (1980), and Robins et al. (1986).

The fish transect data were entered into a custom AGRRA Excel spreadsheet. REEF provided the RDT data in ASCII format. Using the transects as replicates, the average density (#/100 m²) and size (cm) of each species and family were calculated for each site. Analyses were done at the regional (GC versus LC) and site levels, incorporating reef location (windward, leeward) and benthic parameters when appropriate. The average density and size of each species and family were compared between regions using a t-test after testing the data for normality. Due to confounding factors such as differences in use (e.g., recreation, harvest) and hydrographic features, comparisons between protected (marine park) and unprotected sites were not attempted. The site data were used in a hierarchical cluster analysis using Pearson's similarity index. The similarity matrix was generated using log-transformed density values for each species documented in at least three (10%) of the sites; the other 22 rare species were eliminated (per Grossman et al., 1982). A two-dimensional multidimensional scaling (MDS) ordination plot was also generated using the similarity matrix.

The transect data were also used to investigate interactions between the fish assemblages and the benthic community. This preliminary investigation was focused on herbivore/algae interactions. A regression was calculated on the densities of parrotfish and surgeonfish against percent absolute macroalgal abundance in quadrats (hereafter macroalgal abundance) and height at each site. Other coral factors (percent live coral cover, average colony height, percent diseased colonies) and environmental (windward/leeward) parameters were also plotted against each fish family. All values were transformed prior to regression (transformations were log+1 for fish density and algal height and arcsine of the square root for proportions).

The RDT survey data provided species lists, frequency of occurrence, and relative abundance estimates. Percent sighting frequency (%SF) for each species was the percentage of all dives in which the species was recorded. An estimate of abundance was calculated as: abundance score = $D \times \%SF$, where the density score (D) for each species was a weighted average index based on the frequency of observations in different abundance categories. Density score was calculated as:

$D = ((n_S \times 1) + (n_F \times 2) + (n_M \times 3) + (n_A \times 4)) / (n_S + n_F + n_M + n_A)$, where n_S , n_F , n_M , and n_A represented the number of times each abundance category (Single, Few, Many,

Abundant) was assigned for a given species. The RDT data were pooled and compared by island using the Wilcoxon Sign Rank test. Only species that were seen in at least 10% of the RDT AGRRA surveys were included in the analysis (103 species), reducing the effect of rare species (Grossman et al., 1982). SYSTAT 7.0 was used for all the analyses.

All expert-level REEF data from GC and LC, including the RDT data collected during the AGRRA expedition, were used to compile a species list of reef fishes for the Cayman Islands (REEF, 2001).

RESULTS

A total of 341 transects (142 - GC; 199 - LC) and 79 RDT surveys (32- GC and 47- LC) documenting 173 species were conducted at 33 reefs (Table 1). The RDT survey data were added to the existing REEF database. The total number of species recorded by REEF experts on the Cayman Islands between 1994 and 2001 was 275 (Appendix A, this paper). When compared with Burgess et al.'s (1994) ichthyofaunal list, the REEF survey data added 58 new species records for a total of 423 reef fishes documented on the Cayman Islands (five freshwater species, 10 deepwater (>300 m) species, and a misidentification (*Stegastes mellis*) listed by Burgess et al. (1994) were not included in this tally). The 25 most common species, according to %SF in the REEF database, are noted in Table 2.

Parrotfish (Scaridae) was the most abundant family recorded during the belt transects (Fig. 2). Average density of snapper (Lutjanidae) on LC was approximately twice that of GC reefs. Size frequency distributions of carnivores (select grouper genera and all snappers) and herbivores [parrotfish ≥ 5 cm, surgeonfish (Acanthuridae), and the

Figure 2. Mean fish density (no. individuals/100 m² \pm sd) for AGRRA fishes in Grand Cayman and Little Cayman. Other = *Bodianus rufus*, *Caranx ruber*, *Lachnolaimus maximus*, *Microspathodon chrysurus*, *Sphyrna barracuda*.

yellowtail damselfish *Microspathodon chrysurus*] are shown in Figure 3. Approximately 75% of the carnivores were less than 30 cm in length, and 85% of the herbivores were less than 20 cm in length. T-tests on these data showed that the average density and size for most species and families did not differ between islands. However, many species were reported in RDT surveys with greater than average abundance on the LC reefs (Wilcoxon Sign Rank $p < 0.0005$). In particular, the sighting frequencies of six species of large groupers were considerably greater in LC (Table 3; Wilcoxon Sign Rank $p < 0.05$). Exceptions included yellowtail snapper (*Ocyurus chrysurus*) and sergeant major (*Abudefduf saxatilis*), two species that become abundant when fed regularly by divers. Fish feeding is much more commonplace on GC reefs (Burgess et al., 1994; personal observations).

Site comparisons at the assemblage level showed no clear, intra-island groupings. However, two distinct clusters were obvious in the MDS plot (Fig. 4A) and, to a lesser extent, in the cluster diagram (Fig. 4B). The only environmental characteristics significantly related to fish density were reef location (windward/leeward) and macroalgal abundance. The windward (high-wave exposure) or leeward/protected windward (low wave-exposure) location of the sites was an important factor in the MDS cluster for all but two of the sites (LC02 and GC30). Leeward sites also had significantly higher macroalgal abundance than windward sites (45% versus 31%, respectively; F-test $p < 0.001$; multiple $R = 0.560$).

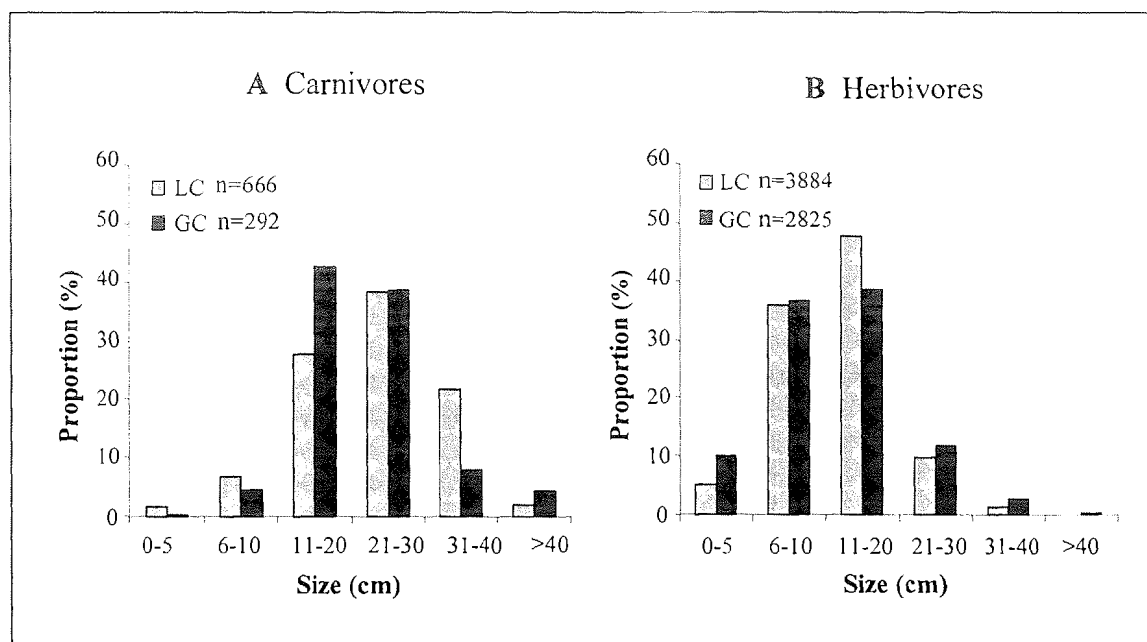

Figure 3. Size frequency distribution of (A) carnivores (all lutjanids, select serranids) and (B) herbivores (acanthurids, scarids ≥ 5 cm, *Microspathodon chrysurus*) in GC (Grand Cayman) and LC (Little Cayman). Total number of individuals counted (n) is given.

Figure 4. (A) MDS ordination plot (left cluster is windward) and (B) hierarchical cluster analysis of AGRRA reef fish transect data in GC (Grand Cayman) and LC (Little Cayman).

Surgeonfish density showed an inverse relationship with macroalgal abundance ($p < 0.01$; $r^2 = 0.209$), whereas parrotfish density was positively related to macroalgal abundance ($p < 0.01$; $r^2 = 0.215$) (Fig. 5). Adding macroalgal height to a multiple regression significantly improved the relationships with macroalgal abundance for parrotfish ($p < 0.001$; $r^2 = 0.413$) and surgeonfish ($p = 0.001$; $r^2 = 0.367$) densities. A strong inverse relationship between parrotfish and surgeonfish densities was also found ($p < 0.001$; $r^2 = 0.384$).

Figure 5. Regression plot between mean parrotfish density (♦) and mean surgeonfish density (□) (no. individuals/100m²) and mean absolute macroalgal abundance by site in the Cayman Islands.

DISCUSSION

The reefs of the Cayman Islands support relatively diverse and abundant fish assemblages. This richness is probably a result of several factors including high local habitat diversity, a significant (34%) area of coastal reserves, and a reef system that is generally in fair condition (Manfrino et al., this volume). However, significant differences were revealed between GC and LC, most likely a result of the greater anthropogenic impacts on GC reefs. Higher harvest pressure on GC was reflected in the lower density and size of large groupers, parrotfishes and snappers (Table 4) and lower sighting frequencies of large groupers (Table 3). Analyses of RDT data indicated that regardless of commercial importance, the average abundance of most fish species was higher on LC, hence other factors, such as coastal development and water pollution, may also adversely impact fish communities on GC.

The site-level transect density data correlated most strongly with relative wave exposure (Fig. 4A,B). Macroalgae were significantly less abundant overall on windward (high-wave exposure) sites than on leeward and protected windward (low-wave exposure) sites, where parrotfish were the most abundant fishes in the transects. It is clear, however, that macroalgal abundance does not by itself adequately explain site-level assemblage composition, given that LC sites had only slight differences between wave-exposed and non wave-exposed sites (Manfrino et al., this volume). The correlation between fish communities at sites with similar wave exposure highlights the effect of physical parameters on fish assemblage structure, and should be taken into consideration in future analyses of fish data for the Cayman Islands.

In a simple system, one might expect the presence and density of herbivorous species to be negatively correlated with algal abundance and height. In other words, a site with many herbivorous fish would have relatively low algal abundance due to grazing. Our analysis at the site level indicates that this expectation holds true for surgeonfish. However, the inverse is evident in parrotfish. This implies either or both of the following: 1) there is a direct or indirect interaction between parrotfish and surgeonfish, or, more generally 2) the dynamic spatial and temporal characteristics of reef fish confound simple relationships between resource availability and fish abundance. Recent work on stoplight parrotfish (*Sparisoma viride*) indicates that whereas there are few, if any, direct interactions between surgeonfish and parrotfish, the use of space on the reef by individual fish is complex (territorial behavior, depth partitioning based on social grouping), and varies as a function of social status and intraspecific interactions (van Rooij et al., 1996a; van Rooij et al., 1996b). Clearly, more research is needed to understand the use of space by reef fish if accurate conclusions are to be drawn from relationships between fish abundance and benthic conditions.

One of the crucial tasks that scientists face in implementing a "reef health scale" using AGRRA data is to determine exactly what indicators within the collected data track health. An additional challenge lies in assessing how to evaluate and analyze the broad and complementary set of information collected on fishes, stony corals, and algae. Results from this paper and others in this volume will provide valuable insight on these issues. Due to the inherently complex nature of coral reef communities, the manner in which AGRRA data will dictate a scale of reef condition is most certainly also complex. The negative relationship between surgeonfish and parrotfish at the site level is a good

example of how community complexity may confound seemingly logical indicators of reef health such as herbivore biomass. Given our results, it is possible that Cayman Island reefs with similar herbivore biomass constituted by predominately different taxa may reflect dramatic differences in benthic conditions. The disparity between grouper abundance between the transect and RDT data and the dramatic increase in species reported in the Cayman Islands that resulted from the RDT surveys (18% based on the published list by Burgess et al., 1994) highlights the importance of using the two complementary visual fish-survey methods.

Because certain fish species dominate the top of coral reef food webs, a baseline of fish community composition and richness provides a useful tool for future assessment of reef health, given that a change in reef communities at lower trophic levels will most likely result in changes in the reef fish community composition (Choat, 1991; Jones et al., 1991). Additionally, because fish tend to be the most charismatic group of reef community members, changes in their community are most likely to be noticed and documented.

ACKNOWLEDGMENTS

The authors wish to thank the Marine Education and Environmental Research Institute (MEERI) and Dr. C. Manfrino for coordinating this immense project. The data collection assistance of K. Hoshino, B. Hansrod, L. Whylen, and P. Hillenbrand is also greatly appreciated. Funding support was provided by the Gilo Family Foundation, American Airlines, Island Air, Little Cayman Beach Resort, Southern Cross Club, the Reef Environmental Education Foundation, the Cayman Islands Department of Tourism and Tortuga Divers. The AGRRA Organizing Committee facilitated financial support as described in the Forward to this volume. The REEF volunteers who have contributed surveys from the Cayman Islands are also appreciated.

¹Site name given if it corresponds to a known Cayman Island Department of Environment buoy.

²Park = Marine Park Area; open = no protection; replen = Replenishment Zone Area

³lee = leeward; wind = windward; pro wind = protected windward

⁴Reef types follow Manfrino et al. (this volume), S&G = spur and groove, High S&G = high profile spur and groove.

⁵Cover values from benthic AGRRA transects (Manfrino et al., this volume)

⁶RDT = Roving Diver Technique

Table 2. Twenty-five most frequently sighted fish species on the Cayman Islands. Data (Sighting Frequency and Density Score) were compiled from the REEF database, using expert sightings from 1994 through 2001 (N=670 RDT Surveys).

Scientific name	Common name	Sighting frequency (%)	Density score ¹
<i>Acanthurus coeruleus</i>	Blue Tang	98	2.8
<i>Thalassoma bifasciatum</i>	Bluehead	97	3.3
<i>Chromis cyanea</i>	Blue Chromis	97	3.8
<i>Stegastes partitus</i>	Bicolor Damselfish	96	3.6
<i>Sparisoma viride</i>	Stoplight Parrotfish	96	2.7
<i>Caranx ruber</i>	Bar Jack	95	2.3
<i>Chromis multilineata</i>	Brown Chromis	95	3.4
<i>Grama loreto</i>	Fairy Basslet	94	3.6
<i>Chaetodon capistratus</i>	Foureye Butterflyfish	94	2.1
<i>Sparisoma aurofrenatum</i>	Redband Parrotfish	93	2.7
<i>Halichoeres garnoti</i>	Yellowhead Wrasse	92	2.7
<i>Canthigaster rostrata</i>	Sharpnose Puffer	92	2.1
<i>Epinephelus cruentatus</i>	Graysby	92	2.1
<i>Lutjanus apodus</i>	Schoolmaster	91	2.4
<i>Ocyurus chrysurus</i>	Yellowtail Snapper	89	2.5
<i>Haemulon flavolineatum</i>	French Grunt	89	2.3
<i>Scarus croicensis</i>	Striped Parrotfish	89	2.4

<i>Clepticus parrae</i>	Creole Wrasse	87	3.7
<i>Melichthys niger</i>	Black Durgon	87	2.8
<i>Mulloidichthys martinicus</i>	Yellow Goatfish	84	2.4
<i>Holacanthus tricolor</i>	Rock Beauty	84	1.9
<i>Stegastes diencaeus</i>	Longfin Damselfish	82	2.3
<i>Epinephelus fulvus</i>	Coney	81	2.1
<i>Stegastes planifrons</i>	Threespot Damselfish	80	2.2

¹See Methods for definition of Density score.

Table 3. Mean percent sighting frequency of select groupers during AGRRA roving diver surveys in LC and GC, Cayman Islands.

Scientific name	Common name	Sighting frequency (%)	
		LC	GC
<i>Mycteroperca bonaci</i>	Black Grouper	7%	3%
<i>Epinephelus striatus</i>	Nassau Grouper	69%	9%
<i>Epinephelus guttatus</i>	Red Hind	44%	21%
<i>Mycteroperca tigris</i>	Tiger Grouper	50%	12%
<i>Mycteroperca venenosa</i>	Yellowfin Grouper	22%	0%
<i>Mycteroperca interstitialis</i>	Yellowmouth Grouper	6%	3%

Table 4. Density and length (mean \pm standard deviation) of AGRRA fishes, and macroalgal index values for LC and GC, Cayman Islands.

Island	Herbivores		Carnivores			Macroalgal index ²
	Acanthuridae	Scaridae (≥ 5 cm)	Haemulidae (≥ 5 cm)	Lutjanidae	Serranidae ¹	
LC density (#/100m ²)	10.67 \pm 7.22	21.20 \pm 7.56	4.59 \pm 5.98	3.17 \pm 3.61	2.38 \pm 0.96	105
LC length (cm)	11.85 \pm 2.08	15.87 \pm 2.67	19.45 \pm 2.58	27.78 \pm 3.42	19.11 \pm 3.02	
GC density (#/100m ²)	8.35 \pm 6.66	22.13 \pm 7.04	8.72 \pm 10.04	1.86 \pm 2.04	2.00 \pm 0.67	32
GC length (cm)	12.02 \pm 1.60	15.33 \pm 2.19	19.21 \pm 1.36	28.58 \pm 7.29	18.95 \pm 1.92	

¹*Epinephelus* spp. and *Mycteroperca* spp.²Macroalgal index = absolute macroalgal abundance x canopy height.

Appendix A. Cayman Islands Species List. Data compiled from the REEF database, using expert sightings from 1994 through 2001. A total of 670 expert surveys (32- Cayman Brac; 258- Little Cayman; 380- Grand Cayman) reported 276 species. For each species, percent sighting frequency (%SF) and density score (DEN) are given. Fifty-eight species previously unreported from the Cayman Islands are listed and indicated by an asterisk (*).

¹Species Only, those seen during REEF surveys with no abundance estimates.

Plate 6A. "Recent mortality," as in this *Montastraea annularis* lobe, is defined as any non-living parts of the coral in which the corallite structures are white and either still intact or covered by a thin layer of algae or fine mud. (Photo Kenneth W. Marks)

Plate 6B. Recent mortality resulting from parrotfish bites, most commonly observed in the *Montastraea annularis* species complex (as shown) and *Colpophyllia natans*, is characterized by partial loss of the skeleton along with the overlying living tissues. (Photo Robert S. Steneck)
